

Frame the session: we are replacing fragmented access channels with one governed pipeline from catalogue to credential.

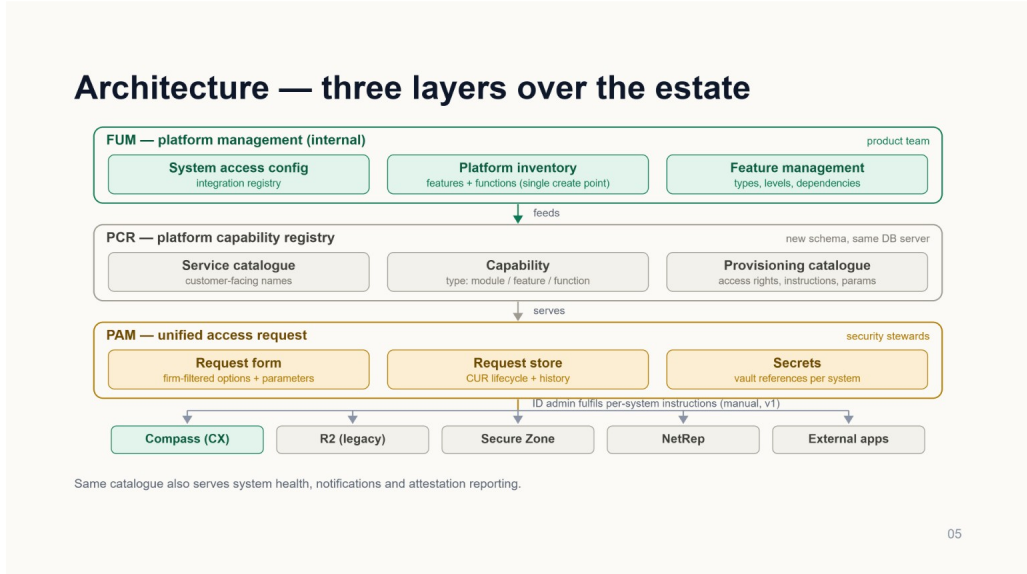

Three incidents is the number from the handover; the trading incident is the one leadership already knows about.

The ownership strip settles the who-owns-the-registry debate: product activation, supported by FUM, executed by SSA.

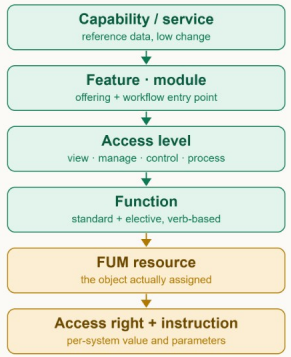

Close the exec section by asking for the four decisions; everything after this slide is for the build teams.

Manage integration ships first because feature management references it; PCR is new tables in a separate schema on the existing server.

The translation chain and PCR entities

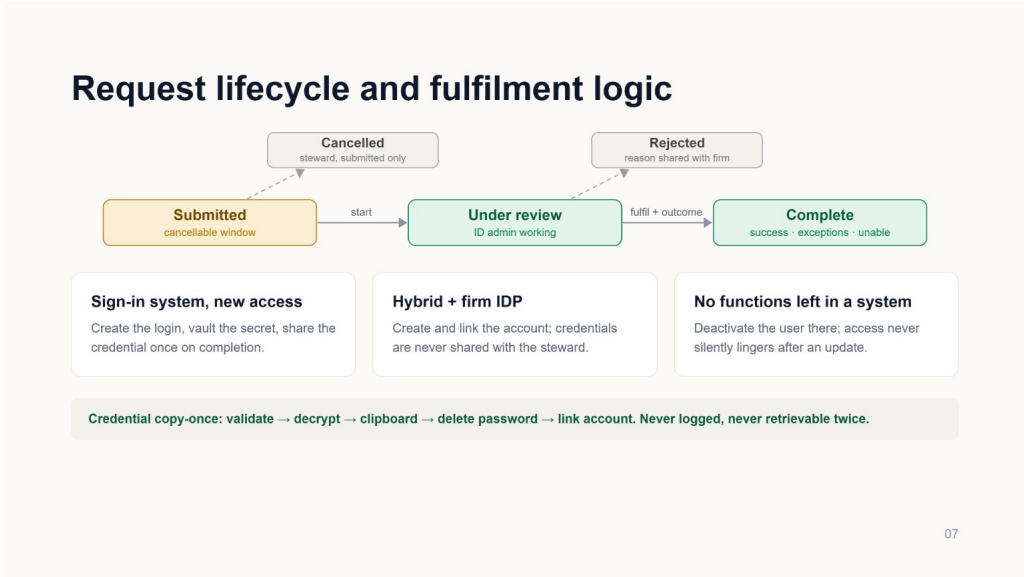

Entity	Holds
Request	status, lifecycle history, supplied parameter values
Capability	name + type: module / feature / function (one table)
Access right	the generic grant — role, group, permission, licence, code
Instruction	per-system steps; optional required parameter
Secret	request × system → vault reference, released on completion

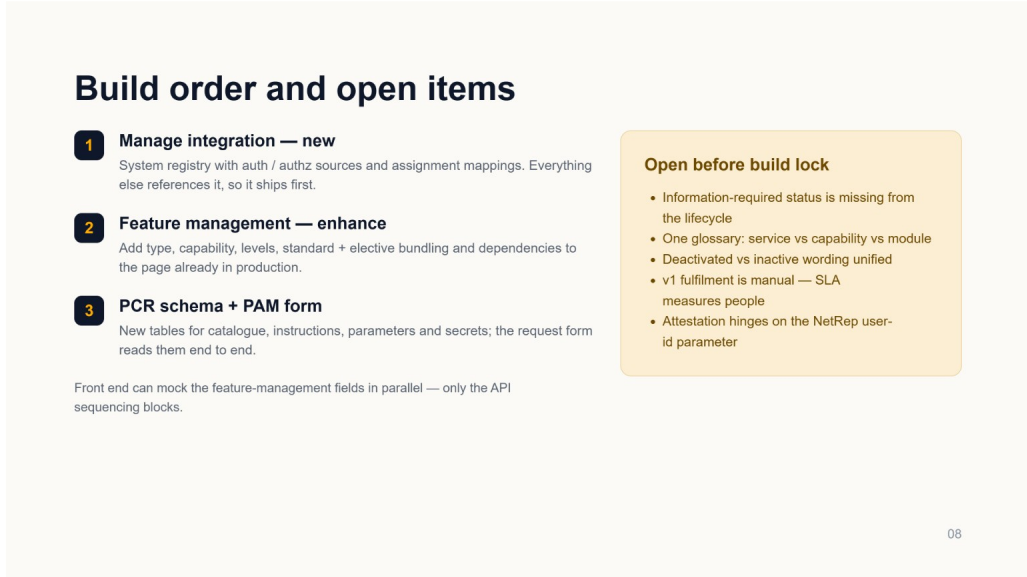

06

All tables are new, in a separate schema on the same database server as FUM. Generic on purpose: NetRep, Secure Zone and R2 share none of Compass's vocabulary, so the registry speaks

The one typed capability table is the architect's deliberate simplification; required parameters are collected on the form before submission.

The plan is a diff of current versus requested assignments per system; these three rules fall out of auth type plus that diff.

Close with the ask to development: estimate against this order, flag anything the open-items list changes.
